

Fiber bundles

Typical transmittance of glass and quartz fibers, length 2 m

Fiber bundles

- Large diameters
- Customized bundles for individual applications
- UV – NIR

Optical fibers are typically used to carry light to or from areas which are difficult to reach.

We offer fiber bundles made of glass or quartz fibers with approx. 100 µm cores. A bundle may have 50 – 500 fibers depending on diameter. Because of the large optical bundle diameter these are particularly used for light capture of large sources such as halogen lamps or reflector lamps. The glass bundles transmit in the 380 – 1600 nm range, the acceptance cone is 68°. The quartz bundles transmit from 200 – 1200 nm and 1500 – 1800 nm, the acceptance cone is 25°.

Our glass fiber bundles come in a protective metal hose (chrome plated) with anodized aluminium end sleeves. The thermal capacity is approx. 120 °C. Our quartz bundles come in a metal spiral hose with glass fiber sheathing and a silica jacket. This highly flexible hose offers great protection against bending, traction and torsion. The bundles withstand up to 180 °C.

Our standard fiber bundles are of non-random type (but they can not be used for imaging purposes). For better uniform output we can supply randomized bundles at an extra charge.

Accessories

You can put an 11 mm adapter on the end terminals to fit most accessories like fiber collimating optics and couplers for light sources, monochromators and detectors.

By the way

The price of quartz fiber bundles is determined by the material, which is why they can be pretty costly. To reduce the price, we offer customized solutions for your individual applications (i.e. optimal diameter, length or thermal capacity of up to 400 °C).
