

# Large core optical quartz fibers

Typical transmittance of large core quartz fibers, length 2 m

- Small diameter
- Transmittance of 200 nm - 2 μm

As opposed to fiber bundles, large core quartz fibers are single fibers with a core diameter of 100 μm - 1 mm. The great advantage of large core quartz fibers compared to fiber bundles is the high and continuous transmittance of 200 - 2000 nm even with long distance applications. These large core quartz fibers are particularly useful for coupling to smaller light sources such as 50 - 150 W arc lamps or for coupling light to the input of monochromators.

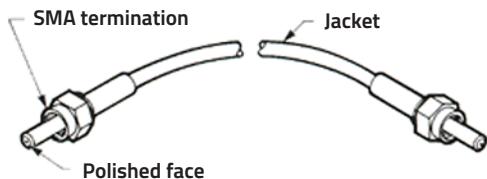

## We offer three different types:

- UV-VIS for 200 - 2000 nm
- VIS-NIR for 500 - 2000 nm with a water free silica core
- UV-VIS solarization resistant for applications below 260 nm.

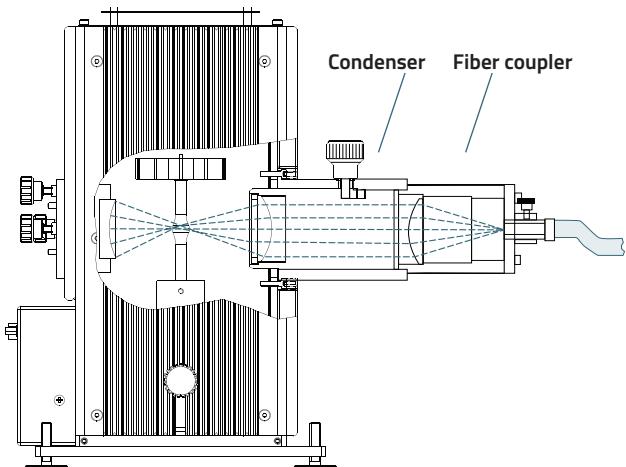

UV radiation below 260 nm causes "solarization" of fused silica (quartz). High energy UV photons generate defects in the glass, which reduce transmittance particularly in the UV. Fibers do not transmit below 260 nm after a prolonged exposure to UV-radiation.

A special production process helps reduce this effect for a certain period of time. Our solarization-resistant fibers can withstand these damaging effects for periods of up to 18 months.

All fibers come with SMA terminations on both ends in a protective metal spiral tube with glass cladding and a silicone jacket. The highly flexible hose offers great protection against bending, traction and torsion.
